Rationale and evidence on the use of tocilizumab in COVID-19: a systematic review

A. Cortegiani, M. Ippolito, M. Greco, V. Granone, A. Protti, C. Gregoretti, A. Giarratano, S. Einav, M. Cecconi

Abstract

Background: Tocilizumab is an IL-6 receptor-blocking agent proposed for the treatment of severe COVID-19. The aim of this systematic review was to describe the rationale for the use of tocilizumab for the treatment of COVID-19 and to summarize the available evidence regarding its efficacy and safety.

Methods: MEDLINE, PubMed, EMBASE, pre-print repositories (bioRxiv and medRxiv) and two trial Registries were searched for studies on the use of tocilizumab in COVID-19 or SARS-CoV-2 infection, viral pneumonia, and/or sepsis until 20th June 2020.

Results: We identified 3 indirect pre-clinical studies and 28 clinical studies including 5776 patients with COVID-19 (13 with a comparison group, 15 single-arm). To date, no randomized trials have been published. We retrieved no studies at low risk of bias. Forty-five ongoing studies were retrieved from trial registries.

Abbreviations: AIFA, Agenzia Italiana del Farmaco; ARDS, Acute respiratory distress syndrome; COVID-19, Coronavirus disease 2019; CPAP, Continuous positive airway pressure; CRS, CAR-T cell-induced cytokine release syndrome; GCA, Giant cell arteritis; ICTRP, International Clinical Trials Registry Platform; IDSA, Infectious Diseases Society of America; IMV, Invasive mechanical ventilation; NIH, U.S. National Institutes of Health; NIV, Noninvasive mechanical ventilation; pJIA, Pediatric juvenile idiopathic arthritis; RA, Rheumatoid arthritis; SIMT, Italian Society of Infectious and Tropical disease; sJIA, Juvenile idiopathic arthritis; TNF, Tumor necrosis factor; WHO, World Health Organization.
Introduction

The search for the holy grail of medical treatment for COVID-19 (Coronavirus Disease-2019) has led researchers to propose, among other options, the use of IL-6 receptor blocking agents for treatment of symptomatic patients.\(^1\) With a death toll of nearly 400,000 worldwide and nearly 7 million known cases,\(^2,3\) the current lack of targeted effective medication and ongoing reliance on supportive treatment alone remains a major cause of concern.\(^1\)

Patients with the most severe COVID-19 symptoms (i.e., severe lung damage, septic shock and multiple organ failure) also exhibit what seems to be a hyper-inflammatory syndrome.\(^4\) Early serology analyses identified higher IL-6 serum levels in patients with severe COVID-19 (particularly non-survivors) when compared to patients with mild and moderate disease.\(^5,6\) As it has been proposed that elevated IL-6 levels may be associated with greater disease severity, the assumption is that they are also associated with worse clinical outcomes and vice versa. This assumption underlies the current interest in anti-inflammatory therapies for the treatment of COVID-19.\(^7\)

One of the IL-6 receptor blocking agents proposed for treatment of COVID-19, tocilizumab, was introduced in the early 2000’s for treatment of autoimmune disorders such as refractory rheumatoid arthritis and systemic juvenile idiopathic arthritis (SJIA),\(^8,9\) and has been approved by the FDA since 2017 for treatment of the cytokine release syndrome (CRS) that may occur following some forms of immunotherapy (e.g. CAR-T).\(^10\) The aim of this review was to describe the rationale and summarize the available evidence, direct and indirect, regarding the use of tocilizumab for treatment of SARS-CoV-2 infection and to identify and describe ongoing clinical trials with this drug.

Methods

A preliminary search conducted prior to formal study initiation suggested the evidence on the topic is likely to be limited, and yet patients are already receiving the drug, making the issue urgent. Therefore, the protocol of this systematic review was not registered.

PICO question

We sought information regarding the use of tocilizumab (I) for treatment of COVID-19, SARS-CoV-2 infection, viral pneumonia, and/or sepsis in any population (adults and children) or laboratory model (P) with or without a comparator (C). We aimed to describe any treatment outcome whether solicited or unsolicited (O).

Search methods and article/trial inclusion/exclusion criteria

We conducted a systematic search of the MEDLINE, PubMed and EMBASE databases from inception to 20th June 2020. We sought pre-clinical and clinical studies addressing the use of tocilizumab for treating COVID-19, SARS-CoV-2 infection, viral pneumonia, and/or sepsis. Our search included the keywords ‘tocilizumab’, ‘covid-19’, ‘coronavirus’, ‘sepsis’, ‘pneumonia’, and ‘viral infection’ as exact phrases and a combination of subject headings according to databases syntax. We also searched the references of retrieved papers for additional potentially relevant papers. In order to find prepublication manuscripts, we surveyed the pre-print repositories biorXiv and medRxiv from inception to 20th June 2020 for clinical or pre-clinical studies about the use of tocilizumab in COVID-19 or SARS-CoV-2 infection, viral pneumonia, and/or sepsis. No language restrictions were imposed in any of the searches. Finally, to identify clinical trials studying treatment with tocilizumab for COVID-19, SARS-CoV-2 infection, viral pneumonia, and/or sepsis, we sought trials registered prior to 20th June 2020 in the Chinese Clinical Trial Registry and Clinicatrial.gov. The databases and the trial registries were all screened independently and in duplicate by two of the authors (MI, VG).

In the second stage, the abstracts of all potentially relevant papers and pre-publication manuscripts were screened to identify relevant papers to be downloaded in full. After downloading potentially relevant articles, case reports, case series and reviews were excluded. Discrepancies and doubts regarding the relevance of papers downloaded in full were resolved by discussion and consensus with two additional authors (AC, MG).

Risk of bias assessment

Two of the authors (AC, MI) assessed the risk of bias (RoB) of the included studies independently and in duplicate. Disagreements over RoB were resolved by consensus or, if necessary, adjudicated by a third author (AG). The ROBINS-I tool (Risk Of Bias in Non-randomized Studies of Interventions) was used for nonrandomized studies with a comparison group.\(^11\) The Newcastle Ottawa Scale (NOS) was used for single-arm nonrandomized studies.\(^12\) The domains were rated in accordance with the requirements of the assessment tool used, with the lowest score achieved predominating as accepted. We used the Risk-of-Bias VISual-

Figure 1 PRISMA flow-chart. The figure shows the PRISMA flow-chart with inclusion/exclusion process in details.

Results

The initial search identified 2071 records from MEDLINE, PubMed and EMBASE, pre-print repositories and other sources. After screening of titles and abstracts, removal of duplicates and evaluation of the additional sources retrieved, overall 31 published peer-reviewed papers and preprint non peer-reviewed papers were included (see the PRISMA flow diagram, available in Fig. 1 for the study selection process). Three papers described preclinical studies and 28 papers described clinical studies. The characteristics of the clinical studies included were summarized (see Table 1). In addition, forty-five ongoing clinical studies were retrieved from the trial Registries. These too were tabulated (see Table A1, Appendix A).

Pre-clinical studies and rationale

The hypothetical justification for treating patients with tocilizumab in the context of COVID-19 stems from indirect findings. These include several pre-clinical studies describing a beneficial effect in cellular and murine models of sepsis and influenza.15-17

In a cell model of sepsis (Human monocyte cell line THP-1), tocilizumab reduced the expression of TNF and IL-10, down-regulated inflammasome activation (reduced levels of NLRP3 and CASP1) and inhibited monocyte phagocytic activity. The authors of the study suggested that if suppressing the ‘cytokine storm’ is important when treating sepsis, these effects may be beneficial.15

Tocilizumab has also been evaluated in a murine model of Influenza A virus infection. Mice were anesthetized, intubated, and infected with mouse-adapted H1N1. The tocilizumab treated group (8 mg/kg 24 h before infection) and the controls were compared. Reduced skeletal muscle weakness (measured as digital grip strength), preserved muscle weight and increased short-term and long-term mortality were registered in the treated group, in comparison with controls. The mice manifesting distress were sacrificed and their deaths were also recorded as mortality.16

In a rat model of sepsis-induced acute lung and kidney injury, tocilizumab (4–8 mg/kg) reduced mortality. The authors also observed normalization of persistently high

The table shows the main characteristics of the included studies.
ARDs, acute respiratory distress syndrome; BCRSS, Brescia COVID-19 Respiratory Severity Scale; CI, confidence interval; COVID-19, coronavirus disease 2019; HR, hazard ratio; ICU, intensive care unit; IQR, interquartile range; mITT, modified intention to treat; OR, Odds ratio; SARS, severe acute respiratory syndrome; TCZ, tocilizumab; USA, United States of America.
serum levels of IL-6 in septic rats after treatment with tocilizumab and improved lung wet/dry weight ratio and total protein content in the treatment group, in comparison with the sham group.\textsuperscript{10}

Clinical studies

We retrieved 13 published clinical studies\textsuperscript{18–20} and 15 preprint (i.e. pre peer review) clinical studies,\textsuperscript{31–45} respectively evaluating 1396 and 4380 patients, for a total of 5776 patients. The main characteristics of the included clinical studies are presented in Table 1. Only three peer reviewed papers\textsuperscript{22,26,27} and five prepublications\textsuperscript{33,35,40,44} were multicenter studies. Thirteen studies included more than 100 patients, but in these studies the number of patients receiving tocilizumab was not large. One published trial included 112 patients but only one in five patients (n = 21) received tocilizumab.\textsuperscript{24} Another published trial included 111 patients among whom less than half (n = 49) were treated.\textsuperscript{25} One prepublication included 547 patients of which a third (n = 134) were treated\textsuperscript{26} and another included 1229 patients of which 260 received tocilizumab.\textsuperscript{33} Seven of the 13 published papers and six of the 15 prepublications presented no comparator.

The risk of bias assessments are shown in Fig. 2 (nonrandomized studies with comparison) and in Appendix A, Table A2 (nonrandomized single-arm studies). Ten studies were at moderate and five at serious risk of bias (ROBINS-I); thirteen studies were judged to be of ‘poor quality’ (NOS). None of the studies were assessed as having a low risk of bias.

Discussion

The mechanism of action and pharmacological properties of tocilizumab

Tocilizumab is a humanized monoclonal antibody capable of interfering with the IL-6 soluble and membrane binding site of the receptor (IL-6R), thereby blocking the assembling of the activated complex with the transmembrane protein (gp130-IL-6-sLR). Tocilizumab is also able to block IL-6 trans-signaling\textsuperscript{46} which is strongly related to the pro-inflammatory effects of IL-6 (e.g. release of acute phase proteins). Tocilizumab has a non-linear pharmacokinetic profile, with a dose-response curve that plateaus at an approximate dose of 800 mg.\textsuperscript{46} The half-life of tocilizumab is dose-dependent and comparable to the half-life of IgG1.\textsuperscript{47}

Interleukin-6 (IL-6) and COVID-19

IL-6 is a pleiotropic cytokine secreted by neutrophils, monocytes and macrophages and involved in the inflammatory response. It has a soluble (sIL-6R) and a membrane binding site (mIL-6R), constituting its receptors. IL-6 can bind its mIL-6R at low doses or, at higher doses, its sIL-6R (trans-signaling), creating the activated complex with gp130 protein.\textsuperscript{46} Signaling is mediated by Janus kinases (JAK) and Ras/mitogen-activated protein kinase (MAPK)/NF-κB-IL-6.\textsuperscript{48} IL-6 promotes B and T cells differentiation, acute phase protein production and osteoclast activation.\textsuperscript{46} High levels of IL-6 have been listed among the main features of cytokine storm and cytokine release syndrome (CRS), both of which are characterized by an exaggerated release of pro-inflammatory cytokines and potentially life-threatening multiorgan damage.\textsuperscript{48} IL-6 also seems to be involved, through these mechanisms, in the pathophysiology of COVID-19, especially in the most severe forms of the disease.\textsuperscript{3,6,49,50} Furthermore, elevated levels of IL-6 have been associated with a hypercoagulable state in both animals and humans\textsuperscript{51,52} and coagulopathy is another characteristic of patients with COVID-19 at high risk of death.\textsuperscript{53}

Evidence on efficacy and safety of tocilizumab for COVID-19

The current systematic review shows that although indirect preclinical data suggests rationale for using tocilizumab and observational studies suggest that treatment with tocilizumab may be associated with more favorable outcomes compared to standard care in patients with severe or critical COVID-19, up till now no RCTs have been published or made available pre-print regarding either the effectiveness or the safety of tocilizumab in the context of COVID-19.

The effects of tocilizumab against IL-6 related pro-inflammatory and pro-coagulant status\textsuperscript{2} partially explain its potential role in COVID-19.\textsuperscript{54} However, it is worth remembering that there is yet no evidence that suppressing the physiological inflammatory response to the virus is indeed beneficial. Previous experience with pharmacological inflammatory response modulation in patients with ARDS\textsuperscript{55} and sepsis\textsuperscript{56} have been notoriously unsuccessful.

Several observational studies have examined whether tocilizumab has any effect in patients with COVID-19. Although many of the patients included in these studies had severe or critical disease and many were admitted to ICUs, drawing conclusions from the findings of these studies is a leap of faith, given that most had small sample sizes and high or moderate risk of bias, mostly due to confounding. The identified studies also varied in dosing (single or double), and drug availability issues emerged in some centres, which may have influenced both sample sizes and study designs. Finally, the literature suggests the presence of two phases in the pathophysiology of COVID-19. An early phase characterized by a high viral load and limited systemic impairment, and a late phase, with elevated cytokine levels and a hyperinflammatory state.\textsuperscript{4} Regarding the timing of drug administration, that could therefore potentially determine treatment outcomes, a pre-print study evaluated the effect of early vs late administration of the drug on the outcomes, but the association remains unclear and understudied.\textsuperscript{55} The authors found that for each additional day of delay from the admission to tocilizumab administration, the odds of receiving mechanical ventilation independently increase by 21% (95% CI: [1.08, 1.38], p = 0.002).\textsuperscript{55}

Clinical studies on patients with COVID-19 have also evoked some safety concerns. The risk of secondary infection complications is unclear. Among the studies with a comparison group, six found a higher rate of infections among treated, compared to untreated,
Rationale and Evidence on the use of Tocilizumab in COVID-19

patients.\textsuperscript{19,22,25,31,32,41} Hepatotoxic effects, neutro- and thrombocytopenia and intestinal perforation have also been described.\textsuperscript{57-59} This is worrying, particularly given that data from a clinical study promoted by the Italian agency for medicines (Agenzia Nazionale del Farmaco - AIFA) suggests no significant benefit in terms of either mortality (3.3\% vs. 3.2\%) or ICU admission (10.0\% vs 7.9\%) in patients not requiring mechanical respiratory support, when treated with tocilizumab vs. controls.\textsuperscript{60}

Recommendations ad ongoing studies

Several clinical practice guidelines already include tocilizumab as a therapeutic option for COVID-19. The most recent Chinese guideline\textsuperscript{61} suggests tocilizumab, at a dose of 4–8mg/kg, for patients with extensive lung lesions and for severe cases with increased levels of IL-6 or with complications.\textsuperscript{51} The Italian Society of Infectious and Tropical disease (SIMIT - Lombardy section),\textsuperscript{62} recommends
selection of patients who have recovered from the initial high viral load (i.e. afebrile from >72 h or with symptoms for >7 days), those with high IL-6 levels (>40 pg/mL), those with increasing levels of D-dimer, C-reactive protein, ferritin or fibrinogen levels and those needing ventilation support (CPAP, NIV or IMV) for treatment with tocilizumab. However, both the *Surviving Sepsis Campaign: Guidelines on the Management of Critically Ill Adults with Coronavirus Disease 2019 (COVID-19)* and the U.S. National Institutes of Health (NIH) state that the evidence does not suffice to issue recommendations regarding the use of tocilizumab for COVID-19.\(^53,64\) The World Health Organization (WHO)\(^65\) and the Infectious Diseases Society of America (IDSA)\(^66\) both recommend that tocilizumab only be administered within the context of a clinical trial.

Our search identified 45 registered ongoing trials, including 18 multicentre randomized trials in several countries across 4 continents. The details of the studies underway are provided in Appendix A (Table A1). The results of these trials will hopefully provide sufficient data regarding the role of tocilizumab in the context of COVID-19.

**Conclusion**

Although basic science suggests rationale for administration of IL-6 receptor antagonists to patients with COVID-19, the clinical evidence regarding the efficacy and safety of tocilizumab for COVID-19 remains observational only and is methodologically flawed. As concerns have also been raised regarding the possibility of secondary infection, the use of this drug should be limited to the context of a clinical trial and accompanied by ethical committee approval and/or informed consent, as well as appropriate monitoring for side effects.
